# Framework

- In this course we will talk about **languages** – what they are and how we can define them – and about **compilers** – tools that recognize them and allow you to perform actions as a result of that process.

- If you had to define **language** how would you do it?
  - Allows **express, transmit and receive ideas**.
  - **Communication** between people or living beings in general.
  - Includes communication with and between machines.
  - Requires several **communicating entities**, a code and rules for the communication to be intelligible.
  - Requires the use of (at least) one medium or **communication channel** (sound, text, ...).
- Required: coding and a set of common rules, and interlocutors who know them.
- Let's look at some natural languages as an example.
- Different words, in different languages, can have the same meaning:
  - *"adeus", "goodbye", "au revoir",*  

- On the other hand, there are also words that are the same with different meanings (depending on the context):
  - *hill, river, path, ...*

- Different languages may use different symbols (letters or characters), or share many of them.
- Comprehension of a word is done letter by letter, but this does not happen with a text.
- Thus, we can see a natural language like Portuguese as being composed of more than one language:
  - One that spells out the rules for building words from the alphabet of letters:

$a + d + e + u + s \rightarrow \text{goodbye}$

- And another one that contains the grammar rules for building sentences from the resulting words from the previous language:

$\text{goodbye} + \text{and} + \text{see you} + \text{tomorrow} \rightarrow \text{goodbye and see you tomorrow}$

In this case, the alphabet ceases to be the set of letters and becomes the set of existing words.

- Inherent in languages is the need to decide whether a sequence of alphabet symbols is valid.
  - **correct:**  
a + d + e + u + s → goodbye  
goodbye + and + until + tomorrow →  
goodbye and see you tomorrow
  - **incorrect:**  
e + d + u + a + s → edes  
until + goodbye + tomorrow + and → see you tomorrow and
- Only valid strings allow correct communication.
- On the other hand, this communication often has an effect.
- Whether that effect is a response to the initial message, or the triggering of any action.

- The languages for communicating with computers – called programming languages – share all these characteristics.
- They differ in that they cannot have any **ambiguity**, and that the triggered actions often be a change in the state of the computational system, which may be linked to entities such as other computers, people, robotic systems, washing machines, etc.
- Let's see that we can define programming languages by well-behaved formal structures.
- Furthermore, we will also see that these definitions help us to implement interesting actions.

Development of programming languages umbilically linked with compilation technologies!

## Compilers

Comprehension, interpretation and/or automatic translation of languages.

# Compilers (Language Processors)

- **compilers** are programs that allow:
  - 1 decide on the correction of sequences of symbols of the respective alphabet;
  - 2 trigger actions resulting from those decisions.
- Compilers are often “limited” to translating between languages.

- This is the case for compilers of high-level programming languages (Java, C++, Eiffel, etc.), which translate the source code of these languages in code of languages closer to the *hardware* of the system computational (e.g. *assembly* or *Java bytecode*).
- In these cases, in the absence of errors, a program composed of executable code is generated directly or indirectly by the computer system:

## Example: Java *bytecode*

```
public class hello
{
    public static void main(String [] args)
    {
        System.out.println ("Hello!");
    }
}
```

```
javac Hello.java
```

```
javap -c Hello.class
```

Compiled from "Hello.java"

```
public class Hello {
    public Hello();
        Code:
        0: aload_0
        1: invokespecial #1 // Method java/lang/Object."<init>":()V
        4: return

    public static void main(java.lang.String []);
        Code:
        0: getstatic #2 // Field java/lang/System.out:Ljava/io/PrintStream;
        3: ldc #3 // String Hello!
        5: invokevirtual #4 // Method java/io/PrintStream.println:(Ljava/lang/String;)V
        8: return
}
```

## Example 2: Calculator

- Source code:

```
1+2*3:4
```

- A possible compilation for Java:

```
public class CodeGen {  
    public static void main(String[] args) {  
        int v2 = 1;  
        int v5 = 2;  
        int v6 = 3;  
        int v4 = v5 * v6;  
        int v7 = 4;  
        int v3 = v4 / v7;  
        int v1 = v2 + v3;  
        System.out.println(v1);  
    }  
}
```

- A possible variant consists of an **interpreter**:

- In this case, execution is carried out instruction by instruction.
- `Python` and `bash` are examples of interpreted languages.
- There are also hybrid approaches where there is compilation of code for a language intermediate, which is then interpreted at runtime.
- The language `Java` uses a strategy like this where the source code is compiled to *Java bytecode*, which is then interpreted by the `Java` virtual machine.
- In general, compilers process source code in *text* format, with a wide variety in the format of the generated code (text, binary, interpreted, ...).

- An interesting feature of high-level language compilation is the fact that that, as in the case of natural languages, this compilation involves more than one language:
  - **lexical analysis**: composition of letters and other characters into words (*tokens*);
  - **parsing**: composition of *tokens* into a suitable syntactic structure.
  - **semantic analysis**: checking – as much as possible – that the syntactic structure has meaning.
- Actions consist of generating the program in the target language and may involve also different stages of code generation and optimization.

- Conversion of the input string into a string of lexical elements.
- This strategy greatly simplifies the grammar of parsing, and allows for an implementation very efficient lexical analyzer (later we will see in detail why).
- Each lexical element can be defined by a tuple with an element id and its value (value can be omitted when not applicable):

```
<token_name , attribute_value >
```

- Example 1:

```
pos = pos + vel * 5;
```

can be converted by the lexical analyzer (*scanner*) into:

```
<id , pos> <=> <id , pos> <+> <id , vel> <*> <int , 5> <;>
```

- In general whitespace, newlines and comments are not relevant in languages programming, so they can be eliminated by the lexical analyzer.

- Example 2: Geometric Processing Language Sketch:

```
distance (0 ,0) (4 ,3)
```

can be converted by the lexical analyzer (*scanner*) into:

```
<distance> <( > <num,0> <,> <num,0> <)>  
<( > <num,4> <,> <num,3> <)>
```

- After the lexical analysis, the so-called syntactic analysis (*parsing*) is carried out, where conformity is verified of the sequence of lexical elements with the syntactic structure of the language.
- In languages that are intended to be syntactically processed, we can always make an approximation to the its formal structure through a representation like *tree*.
- For this purpose, a *grammar* is needed that specifies the desired structure (we will return to this problem later).
- In the example 1 (`pos = pos + vel * 5;`):

- In the example 2 (`distance ( 0 , 0 ) ( 4 , 3 )`):

- Attention is drawn to two characteristics of syntax trees:
  - does not include some lexical elements (which are only relevant to the formal structure);
  - unambiguously define the order of operations (we'll come back to this problem).

- The final part of the compiler's *front end* is *semantic analysis*.
- In this phase, as much as possible, restrictions are checked that are not possible (or even desirable) to be made in the two previous phases.
- For example: check if an identifier was declared, check conformance in the type system of language, etc.
- Note that only constraints with static checking (i.e. at compile time), can be object of semantic analysis by the compiler.
- If in the example 2 there was an instruction for a circle of which the definition of its radius was part, it would not in general be possible, during semantic analysis, to guarantee a non-negative value for this radius (this semantics could only be verified dynamically, i.e., at runtime).

- Uses the parsing syntax tree as well as a data structure called symbol table (based on associative arrays).
- This last phase of analysis should guarantee the success of subsequent phases (generation and eventual code optimization, or interpretation).

- Having guaranteed that the source language code is valid, then we can move on to the intended effects with that code.
- Effects can be:
  - ① simply the indication of source code validity;
  - ② the translation of the source code into a target language;
  - ③ or interpretation and immediate execution.
- In all cases, it may be of interest to accurately identify and locate any errors.
- As most source code is text based, it is usual to indicate not only the instruction but also the line where each error occurs.

## Code generation: example

- In the compilation process, it may be interesting to generate an intermediate representation of the code that facilitates the final generation of code.
- One possible form for this intermediate representation is the so-called *triple address code*.
- For example 1 (`pos = pos + vel * 5;`) we could have:

```
t1 = intfloat(5)
t2 = id(vel) * t1
t3 = id(pos) + t2
id(pos) = t3
```

- This code could then be optimized in the next phase of compilation:

```
t1 = id(vel) * 5.0
id(pos) = id(pos) + t1
```

- And finally, one could generate *assembly* (pseudo-code):

```
LOAD R2, id(vel) // load value from memory to register R2
MULT R2, R2, #5.0 // mult. 5 with R2 and store result in R2
LOAD R1, id(pos) // load value from memory to register R1
ADD R1, R1, R2 // add R1 with R2 and store result in R1
STORE id(pos), R1 // store value to memory from register R1
```

- Languages are for **communicating**.
- A message can be seen as a sequence of **symbols**.
- However, a language does not accept all types of symbols and sequences.
- A language is characterized by a set of symbols and a way of describe valid sequences of these symbols (i.e. the set of valid sequences).
- If natural languages allow for some subjectivity and ambiguity, programming languages require complete objectivity.

- How to define languages in a synthetic and objective way?
- Setting by **extension** is a possibility.
- However, for minimally interesting not only would we have a gigantic description, but also probably an incomplete one.
- Programming languages tend to accept infinite variants of input.
- Alternatively we can describe it as **understanding**.
- One possibility is to use the formalisms linked to the definition of **sets**.

- A set can be defined by **extension** (or enumeration) or by **comprehension**.
- An example of a set defined by extension is the set of binary digits  $\{0, 1\}$ .
- In the definition by comprehension, the following notation is used:

$$\{x \mid p(x)\}$$

or

$$\{x : p(x)\}$$

- $x$  is the variable that represents any element of the set, and  $p(x)$  is a predicate on that variable.
- Thus, this set is defined as containing all values of  $x$  where the predicate  $p(x)$  is true.
- For example:  
$$\{n \mid n \in \mathbb{N} \wedge n \leq 9\} = \{1, 2, 3, 4, 5, 6, 7, 8, 9\}$$

- A **symbol** (or **letter**) is the atomic (indivisible) unit of languages.
- In text-based languages, a symbol will be a character.
- An **alphabet** is a non-empty finite set of symbols.
- For example:
  - $A = \{0, 1\}$  is the alphabet of binary digits.
  - $A = \{0, 1, \dots, 9\}$  is the alphabet of decimal digits.
- A **word** (*string* or string) is a sequence of symbols about a given alphabet  $A$ .

$$U = a_1 a_2 \cdots a_n, \quad \text{com} \quad a_i \in A \wedge n \geq 0$$

- For example:
  - $A = \{0, 1\}$  is the alphabet of binary digits.  
01101, 11, 0
  - $A = \{0, 1, \dots, 9\}$  is the alphabet of decimal digits.  
2016, 234523, 999999999999999, 0
  - $A = \{0, 1, \dots, 0, a, b, \dots, z, @, \dots\}$   
mos@ua.pt, Good morning!

- The **empty word** is a sequence of zero symbols and is denoted by  $\varepsilon$  (epsilon).
- Note that  $\varepsilon$  does not belong to the alphabet.
- An **subword** of a word  $u$  is a contiguous string of 0 or more  $u$  symbols.
- A **prefix** of a word  $u$  is a contiguous string of 0 or more leading symbols of  $u$ .
- An **suffix** of a word  $u$  is a contiguous sequence of 0 or more terminal symbols of  $u$ .
- For example:
  - as is a subword of home, but not a prefix or suffix
  - 001 is prefix and subword of 00100111 but not suffix
  - $\varepsilon$  is prefix, suffix and subword of any word  $u$
  - any word  $u$  is prefix, suffix and subword of itself

Finite automata

- The **closing** (or set of strings) of the alphabet  $A$  named by  $A^*$ , represents the set of all the definable words over the  $A$  alphabet, including the empty word.
- For example:
  - $\{0, 1\}^* = \{\varepsilon, 0, 1, 00, 01, 10, 11, 000, 001, \dots\}$
  - $\{\clubsuit, \diamond, \heartsuit, \spadesuit\}^* = \{\varepsilon, \clubsuit, \diamond, \heartsuit, \spadesuit, \clubsuit\diamond, \dots\}$
- Given an alphabet  $A$ , a **language**  $L$  over  $A$  is a finite or infinite set of valid words defined with  $A$  symbols.  
That is:  $L \subseteq A^*$

- Example languages about the alphabet  $A = \{0, 1\}$ 
  - $L_1 = \{u \mid u \in A^* \wedge |u| \leq 2\} = \{\varepsilon, 0, 1, 00, 01, 10, 11\}$
  - $L_2 = \{u \mid u \in A^* \wedge \forall_i u_i = 0\} = \{\varepsilon, 0, 00, 000, 0000, \dots\}$
  - $L_3 = \{u \mid u \in A^* \wedge u.\text{count}(1) \bmod 2 = 0\} = \{000, 11, 000110101, \dots\}$
  - $L_4 = \{\} = \emptyset$  (emptyset)
  - $L_5 = \{\varepsilon\}$
  - $L_6 = A$
  - $L_7 = A^*$
- Note that  $\{\}, \{\varepsilon\}, A$  and  $A^*$  are languages over the alphabet  $A$  whatever  $A$  is
- Since languages are sets, all mathematical operations on sets apply: meeting, interception, complement, difference, etc.

Pushdown automata

Finite automata

- The **length** of a word  $u$  is denoted by  $|u|$  and represents its number of symbols.
- The length of the empty word is zero

$$|\varepsilon| = 0$$

- It is customary to interpret the word  $u$  as a function to access its symbols (like *array*):

$$u : \{1, 2, \dots, n\} \rightarrow A, \quad \text{com } n = |u|$$

where  $u_i$  represents the  $i$ th symbol of  $u$

- The **reverse** of a word  $u$  is the word, denoted by  $u^R$ , and is obtained reversing the order of  $u$  symbols

$$u = \{u_1, u_2, \dots, u_n\} \implies u^R = \{u_n, \dots, u_2, u_1\}$$

- The **concatenation** (or **product**) of the words  $u$  and  $v$  is denoted by  $u.v$ , or simply  $uv$ , and represents the juxtaposition of  $u$  and  $v$ , i.e., the word consisting of the  $u$  symbols followed by the  $v$  symbols.
- Concatenation properties:
  - $|u.v| = |u| + |v|$
  - $u.(v.w) = (u.v).w = u.v.w$  (associative)
  - $u.\varepsilon = \varepsilon.u = u$  (neutral element)
  - $u \neq \varepsilon \wedge v \neq \varepsilon \wedge u \neq v \implies u.v \neq v.u$  (non-commutative)
- The **power** of order  $n$ , with  $n \geq 0$ , of a word  $u$  is denoted by  $u^n$  and represents the concatenation of  $n$  replicas of  $u$ , that is,  $\underbrace{uu \cdots u}_{n \times}$ .
- $u^0 = \varepsilon$

# Language operations: meeting

- The **meeting** of two languages  $L_1$  and  $L_2$  is denoted by  $L_1 \cup L_2$  and is given by:

$$L_1 \cup L_2 = \{u \mid u \in L_1 \vee u \in L_2\}$$

- For example, if we define the languages  $L_1$  and  $L_2$  over the alphabet  $A = \{a, b\}$ :

$$L_1 = \{u \mid u \text{ starts with } The\} = \{aW \mid w \in A^*\}$$

$$L_2 = \{u \mid u \text{ ends with } The\} = \{wa \mid w \in A^*\}$$

- what will be the result of merging these languages?

$$L = L_1 \cup L_2 = ?$$

- Answer:

$$L = \{w_1 a w_2 \mid w_1, w_2 \in A^* \wedge (w_1 = \varepsilon \vee w_2 = \varepsilon)\}$$

## Language operations: interception

- The **interception** of two languages  $L_1$  and  $L_2$  is denoted by  $L_1 \cap L_2$  and is given by:

$$L_1 \cap L_2 = \{u \mid u \in L_1 \wedge u \in L_2\}$$

- For example, if we define the languages  $L_1$  and  $L_2$  over the alphabet  $A = \{a, b\}$ :

$$L_1 = \{u \mid u \text{ starts with } The\} = \{aW \mid w \in A^*\}$$

$$L_2 = \{u \mid u \text{ ends with } The\} = \{wa \mid w \in A^*\}$$

- what will be the result of the interception of these languages?

$$L = L_1 \cap L_2 = ?$$

- Answer:

$$L = \{awa \mid w \in A^*\} \cup \{The\}$$

## Operations on languages: difference

- The **difference** of two languages  $L_1$  and  $L_2$  is denoted by  $L_1 - L_2$  and is given by:

$$L_1 - L_2 = \{u \mid u \in L_1 \wedge u \notin L_2\}$$

- For example, if we define the languages  $L_1$  and  $L_2$  over the alphabet  $A = \{a, b\}$ :

$$L_1 = \{u \mid u \text{ starts with } The\} = \{aW \mid w \in A^*\}$$

$$L_2 = \{u \mid u \text{ ends with } The\} = \{wa \mid w \in A^*\}$$

- what will be the result of the difference of these languages?

$$L = L_1 - L_2 = ?$$

- Answer:

$$L = \{awx \mid w \in A^* \wedge x \in A \wedge x \neq a\}$$

- or:

$$L = \{awb \mid w \in A^*\}$$

## Operations on languages: completion

- The **complement** of the  $L$  language is denoted by  $\bar{L}$  and is given by:

$$\bar{L} = A^* - L = \{u \mid u \notin L\}$$

- For example, if we define the language  $L_1$  over the alphabet  $A = \{a, b\}$ :

$$L_1 = \{u \mid u \text{ starts with } The\} = \{aW \mid w \in A^*\}$$

- what will be the result of complementing this language?

$$L = \bar{L_1} = ?$$

- Answer:

$$L = \{xw \mid w \in A^* \wedge x \in A \wedge x \neq a\} \cup \{\varepsilon\}$$

- or:

$$L = \{bw \mid w \in A^*\} \cup \{\varepsilon\}$$

# Language operations: concatenation

- The **concatenation** of two languages  $L_1$  and  $L_2$  is denoted by  $L_1.L_2$  and is given by:

$$L_1.L_2 = \{uv \mid u \in L_1 \wedge v \in L_2\}$$

- For example, if we define the languages  $L_1$  and  $L_2$  over the alphabet  $A = \{a, b\}$ :

$$L_1 = \{u \mid u \text{ starts with } The\} = \{aW \mid w \in A^*\}$$

$$L_2 = \{u \mid u \text{ ends with } The\} = \{wa \mid w \in A^*\}$$

- what will be the result of the concatenation of these languages?

$$L = L_1.L_2 = ?$$

- Answer:

$$L = \{awa \mid w \in A^*\}$$

Turing Machine

Linearly bounded  
automata

Pushdown automata

Finite automata

## Operations on languages: potentiation

- The **power** of order  $n$  of the language  $L$  is denoted by  $L^n$  and is defined inductively by:

$$\begin{aligned}L^0 &= \{\varepsilon\} \\ L^{n+1} &= L^n.L\end{aligned}$$

- For example, if we define the language  $L_1$  over the alphabet  $A = \{a, b\}$ :

$$L_1 = \{u \mid u \text{ starts with } The\} = \{aW \mid w \in A^*\}$$

- what will be the result of the power of order 2 of this language?

$$L = L_1^2 = ?$$

- Answer:

$$L = \{a w_1 a w_2 \mid w_1, w_2 \in A^*\}$$

## Operations on languages: Kleene closure

- The **Kleene closure** of the language  $L$  is denoted by  $L^*$  and is given by:

$$L^* = L^0 \cup L^1 \cup L^2 \cup \dots = \bigcup_{i=0}^{\infty} L^i$$

- For example, if we define the language  $L_1$  over the alphabet  $A = \{a, b\}$ :

$$L_1 = \{u \mid u \text{ starts with } The\} = \{aW \mid w \in A^*\}$$

- what will be the Kleene closure of this language?

$$L = L_1^* = ?$$

- Answer:

$$L = L_1 \cup \{\varepsilon\}$$

- Note that for  $n > 1$   $L_1^n \subset L_1$

- Note that in binary operations on sets it is not required that the two languages are defined on the same alphabet.
- So if we have two languages  $L_1$  and  $L_2$  respectively defined on the alphabets  $A_1$  and  $A_2$ , then the alphabet resulting from the application of any binary operation on the languages is:  $A_1 \cup A_2$

Finite automata

- The use of sets to define languages is often not the most appropriate way and versatile to describe them.
- It is often preferable to identify intermediate structures, which abstract parts or important subsets of the language.
- As in programming, many times recursive descriptions are much simpler, without losing the necessary objectivity and rigor.
- This is where we find the **grammars**.
- **grammars** describe languages by comprehension using **formal** and (often) **recursive** representations.
- Seeing languages as sequences of symbols (or words), grammars formally define the **valid** sequences.

Pushdown automata

Finite automata

- For example, in Portuguese the sentence “The dog barks” can be grammatically described by:

phrase	→	subject predicate
subject	→	article noun
predicate	→	verb
article	→	<b>O</b>   <b>Um</b>
noun	→	<b>dog</b>   <b>wolf</b>
verb	→	<b>thief</b>   <b>howl</b>

- This grammar describes 8 possible sentences and contains more information than the original sentence.
- Contains 6 **terminal symbols** and 6 **non-terminal symbols**.
- A non-terminal symbol is defined by an **production** describing possible representations of that symbol, depending on terminal and/or non-terminal symbols.

Automatons  
Turing Machine  
Linearly bounded  
automata  
Pushdown automata  
Finite automata

- Formally, a grammar is a quadruple  $G = (T, N, S, P)$ , where:
  - $T$  is a non-empty finite set called the terminal alphabet, where each element is called the **terminal** symbol;
  - $N$  is a non-empty finite set, disjoint from  $T$  ( $N \cap T = \emptyset$ ), whose elements are designated by **non-terminal** symbols;
  - $S \in N$  is a specific non-terminal symbol called **start symbol**;
  - $P$  is a finite set of **rules** (or productions) of the form  $\alpha \rightarrow \beta$  where  $\alpha \in (T \cup N)^* N (T \cup N)^*$  and  $\beta \in (T \cup N)^*$ , that is,  $\alpha$  is a string of terminal and non-terminal symbols containing at least one non-terminal symbol; and  $\beta$  is a string of symbols, eventually empty, terminal and non-terminal.

- Formally, the previous grammar will be:

$$G = (\{\mathbf{O}, \mathbf{Um}, \mathbf{dog}, \mathbf{wolf}, \mathbf{thief}, \mathbf{howl}\}, \\ \{\text{sentence, subject, predicate, article, noun, verb}\}, \\ \text{phrase}, P)$$

- $P$  is made up of the rules already presented:

phrase  $\rightarrow$  subject predicate  
subject  $\rightarrow$  article noun  
predicate  $\rightarrow$  verb  
article  $\rightarrow$  **O** | **A**  
noun  $\rightarrow$  **dog** | **wolf**  
verb  $\rightarrow$  **thief** | **howl**

- We can describe the sentence “The dog barks” with the following tree (called syntactic).

- Consider the following grammar

$G = (\{0, 1\}, \{S, A\}, S, P)$ , where  $P$  consists of the rules:

$$S \rightarrow 0S$$

$$S \rightarrow 0A$$

$$A \rightarrow 0A1$$

$$A \rightarrow \varepsilon$$

- What will be the language defined by this grammar?

$$L = \{0^n 1^m : n \in \mathbb{N} \wedge m \in \mathbb{N}_0 \wedge n > m\}$$

Pushdown automata  
Finite automata

- Constraints on  $\alpha$  and  $\beta$  allow to define a taxonomy of languages – Chomsky hierarchy:
  - 1 If there is no restriction,  $G$  is designated by **type-0** grammar.
  - 2  $G$  will be of **1-type**, or **context-dependent** grammar, if each rule  $\alpha \rightarrow \beta$  of  $P$  obeys  $|\alpha| \leq |\beta|$  (with the exception that there may also be the empty output:  $S \rightarrow \varepsilon$ ).
  - 3  $G$  will be of **2-type**, or grammar **context-independent**, or **free**, if each rule  $\alpha \rightarrow \beta$  of  $P$  obeys  $|\alpha| = 1$ , that is:  $\alpha$  consists of a single non-terminal.
  - 4  $G$  will be of **3-type**, or **regular** grammar, if each rule has one of the forms:  $A \rightarrow cB$ ,  $A \rightarrow c$  or  $A \rightarrow \varepsilon$ , where  $A$  and  $B$  are non-terminal symbols ( $A$  can be equal to  $B$ ) and  $c$  a terminal symbol. That is, in all productions,  $\beta$  can only have at most one non-terminal symbol always on the right (or, alternatively, always on the left).

# Chomsky hierarchy (2)

- For each of these types different types of machines can be defined (algorithms, automata) that can recognize them.
- The simpler the grammar, the simpler and more efficient the machine that recognizes these languages.

Pushdown automata  
Finite automata

- Each language class of **type- $i$**  contains the language class **type- $(i+1)$**  ( $i = 0, 1, 2$ )
- This hierarchy not only translates the formal characteristics of languages, but also expresses The required computing requirements:
  - 1 **Turing machines** process grammars without restrictions (type-0);
  - 2 **linearly bounded automata** process context-dependent (1-type) grammars;
  - 3 **Pushdown automata** process context-independent grammars (2-type);
  - 4 **finite automata** process regular grammars (3-type).

# Automata

- (Alan Turing, 1936)
- Abstract computing model.
- Allows (in theory) to implement any computable program.
- Relies on a finite state machine, symbol read/write head and on an infinite tape (where these symbols are written or read).
- The read/write "head" can move one position left or right.
- Very important model in the theory of computation.
- Little relevant in the practical implementation of language processors.

## Turing Machine (2)

Possible operations:

- 1 Write symbol to tape;
- 2 Move head one position to the right;
- 3 Move head one position to the left;
- 4 Halt (accept input).

- The finite state machine (FSM) has access to the current symbol and decides the next action to be performed.
- The action consists of the state transition and what is the operation on the tape.
- If no action is possible, the input is rejected.

- Given the alphabet  $A = \{0, 1\}$ , and considering that a non-negative integer  $n$  is represented by sequence of  $n + 1$  1 symbols, let's implement a TM that adds the next ones (i.e. to the right of the current position) two existing integers on the tape (separated only by a 0).
- The algorithm could be simply swapping the 0 symbol between the two numbers for 1, and swapping the last two symbols 1 for 0.
- For example:  $3 + 2$  which corresponds to the following state on the tape (bold symbol is the position of the "head"):  $\dots \mathbf{0}111101110\dots$  (the intended result will be:  $\dots \mathbf{0}111111000\dots$ ).
- Whereas the states are designated by  $E_i, i \geq 1$  ( $E_1$  being the initial state); and the operations:
  - $d$  move one position to the right;
  - $e$  move one position to the left;
  - $0$  write the 0 symbol on the tape;
  - $1$  write the 1 symbol on the tape;
  - $h$  accept and terminate automaton.

## Turing machine: example (2)

- A possible solution is given by the following state transition diagram:

State	Input	
	0	1
$E_1$	$E_1/d$	$E_2/d$
$E_2$	$E_3/1$	$E_2/d$
$E_3$	$E_4/e$	$E_3/d$
$E_4$	--	$E_5/0$
$E_5$	$E_5/e$	$E_6/0$
$E_6$	$E_7/e$	--
$E_7$	$E_1/h$	$E_7/e$

- $E_1 \dots 0111101110 \dots \rightarrow E_1 \dots 0111101110 \dots \xrightarrow{*} E_2 \dots 0111101110 \dots \rightarrow$   
 $E_3 \dots 0111111110 \dots \rightarrow E_3 \dots 0111111110 \dots \xrightarrow{*} E_3 \dots 0111111110 \dots \rightarrow$   
 $E_4 \dots 0111111110 \dots \rightarrow E_5 \dots 0111111100 \dots \rightarrow E_5 \dots 0111111100 \dots \rightarrow$   
 $E_6 \dots 0111111000 \dots \rightarrow E_7 \dots 0111111000 \dots \xrightarrow{*} E_7 \dots 0111111000 \dots$

# Pushdown automata

- "Head" is read-only and supports an unbounded stack.
- Movement of the "head" in one direction only.
- Automata suitable for parsing.
